

## **NetMap Watershed Characterization: Differences Between 10 m Digital Elevation Models and LiDAR DEMs**

### **Topics**

- (1) resolving topography, slide 2
- (2) headwater network density, slide 3
- (3) shallow landslide potential, slides 4-6
- (4) deep seated slide potential, slide 7
- (5) debris flow potential, slide 8
- (6) floodplains and valley floors, 9-13
- (7) habitat modeling (IP), slides 14-14
- (8) Synthetic network generation, road – stream diversions, slide 16

Take this self guided tour.

## Topography

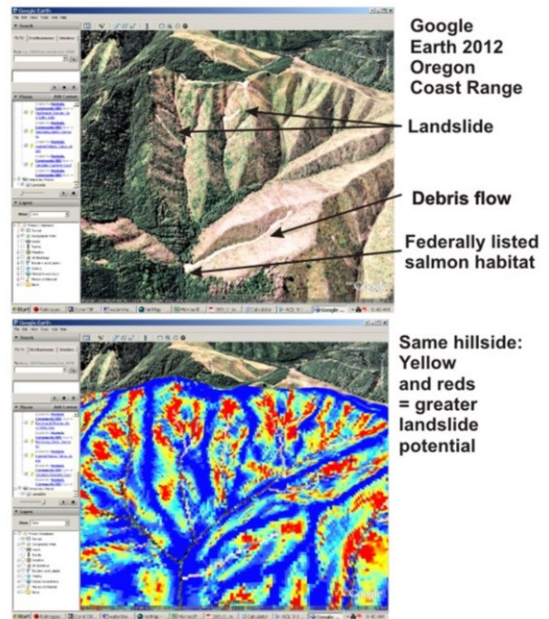

More topographic features can be resolved using LiDAR

## Headwater channel density

LiDAR reveals more headwater streams, many may be ephemeral.

## Shallow landslide potential

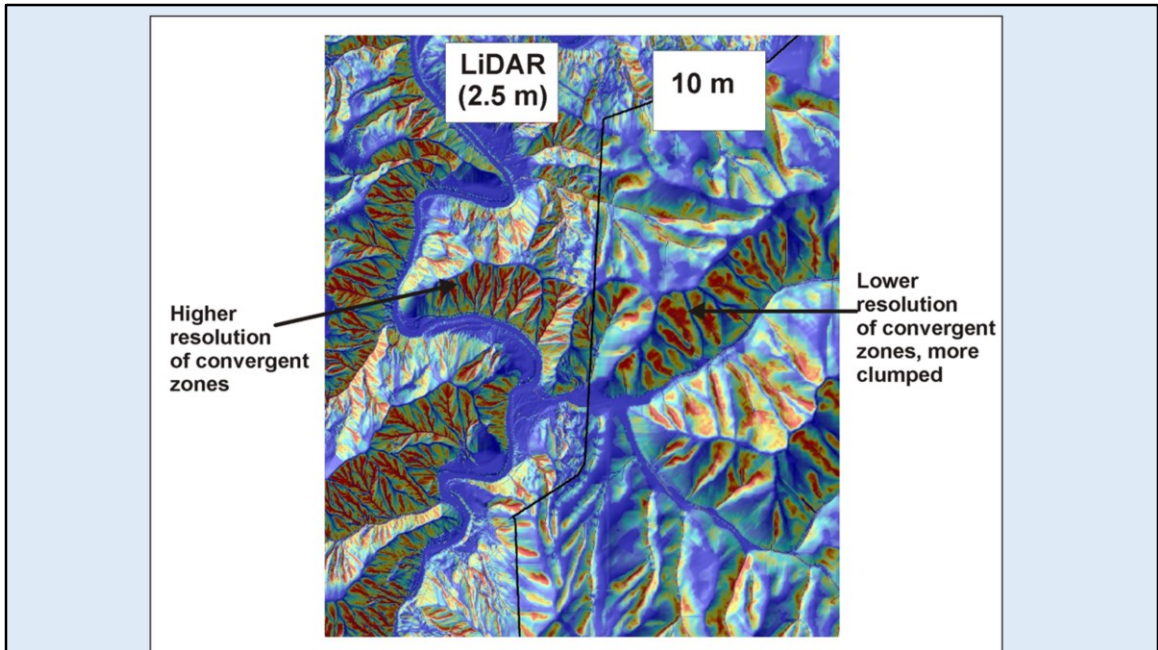

TerrainWorks (www.terrainworks.com)

Another important factor to consider in watershed restoration is landslide potential. Although not considered a restoration priority per se, information on landslide potential could be used in watershed management planning more generally, or restoration planning more specifically, about where erosion risk is the highest and what types of land uses can contribute to it, such as roads. The image above is from the Oregon Coast Range.

### Nehalem shallow landslide Potential

Here is an example of how shallow landslide potential is mapped using either 10 m or LiDAR DEMs in the Nehalem watershed. The LiDAR DEM when used with shallow landslide models provide a much higher spatial resolution, although the 10 m does an adequate job.

LiDAR can resolve individual convergent features (potential landslide sites), whereas the 10 m DEM provides a more coarse (clumped) resolution of the same sites.

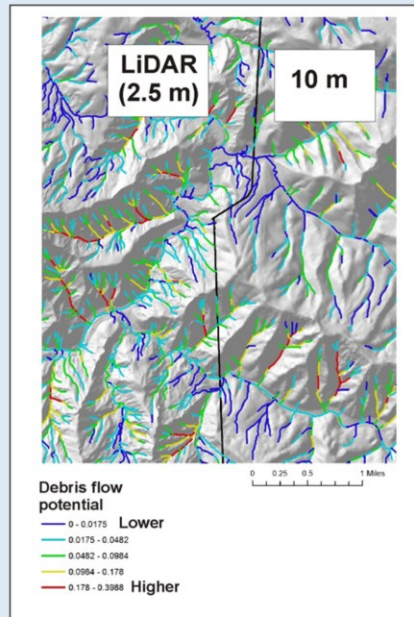

**Deep-seated  
landslide/  
earthflow terrain**

LiDAR can be used to better resolve topographic features associated with existing deep-seated landslides and earthflows (including features that are dormant)

## Debris flow potential

Using LiDAR resolved a higher density of debris flow potential channels; some of the headwater channels may be ephemeral.

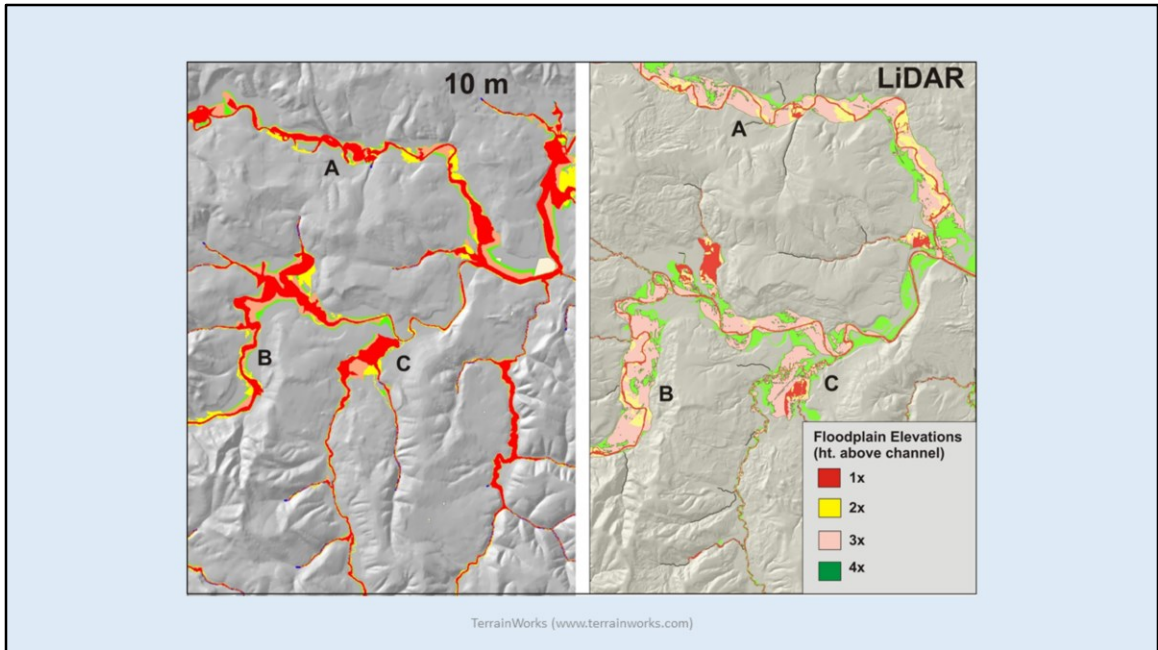

## Floodplains/valley floors

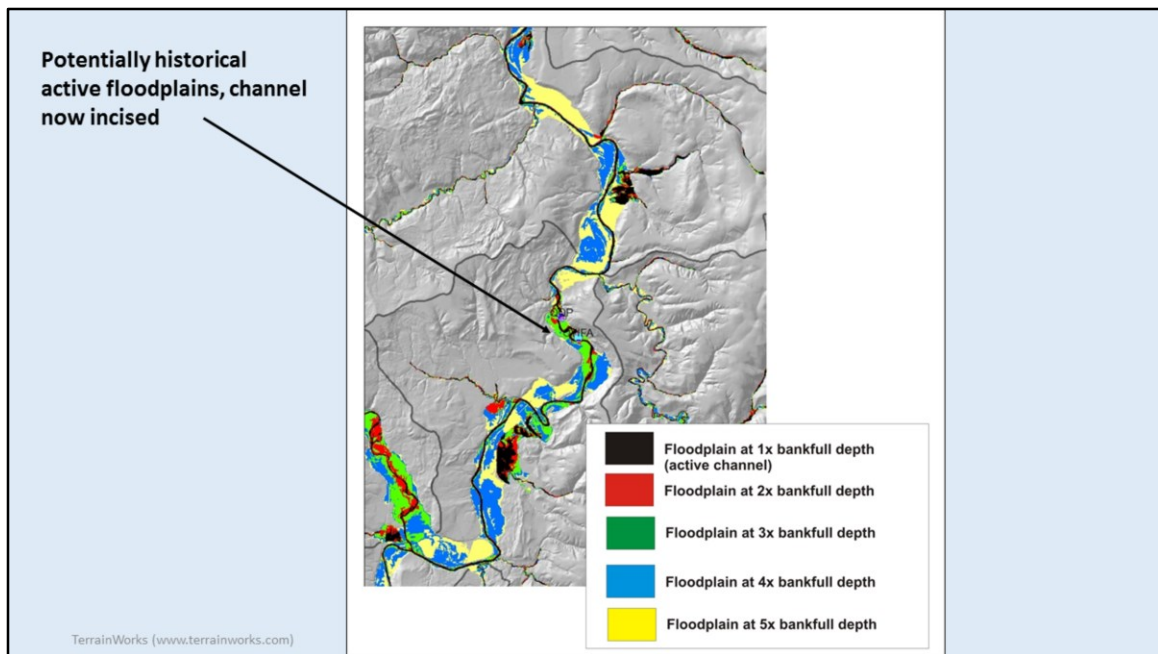

TerrainWorks ([www.terrainworks.com](http://www.terrainworks.com))

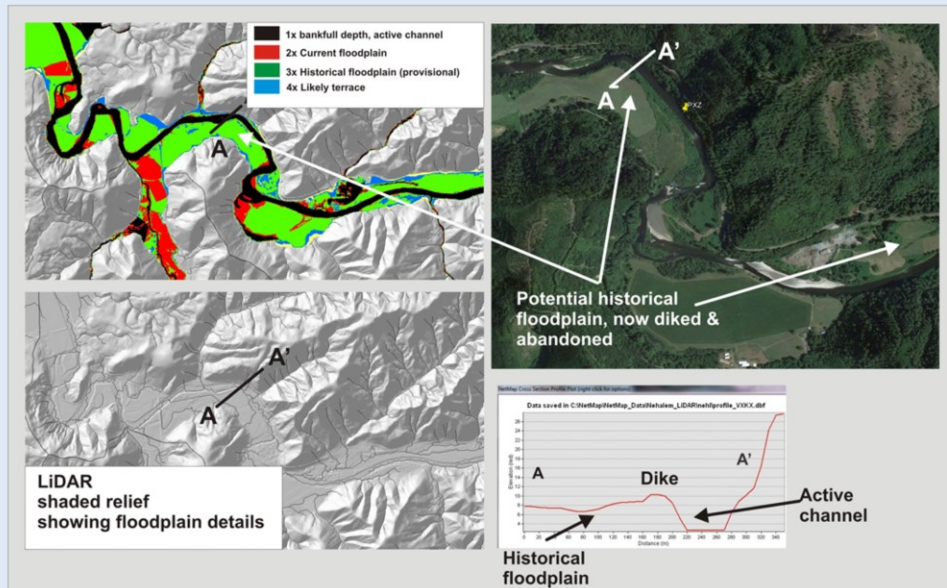

LiDAR improves mapping of floodplains and small tributary features

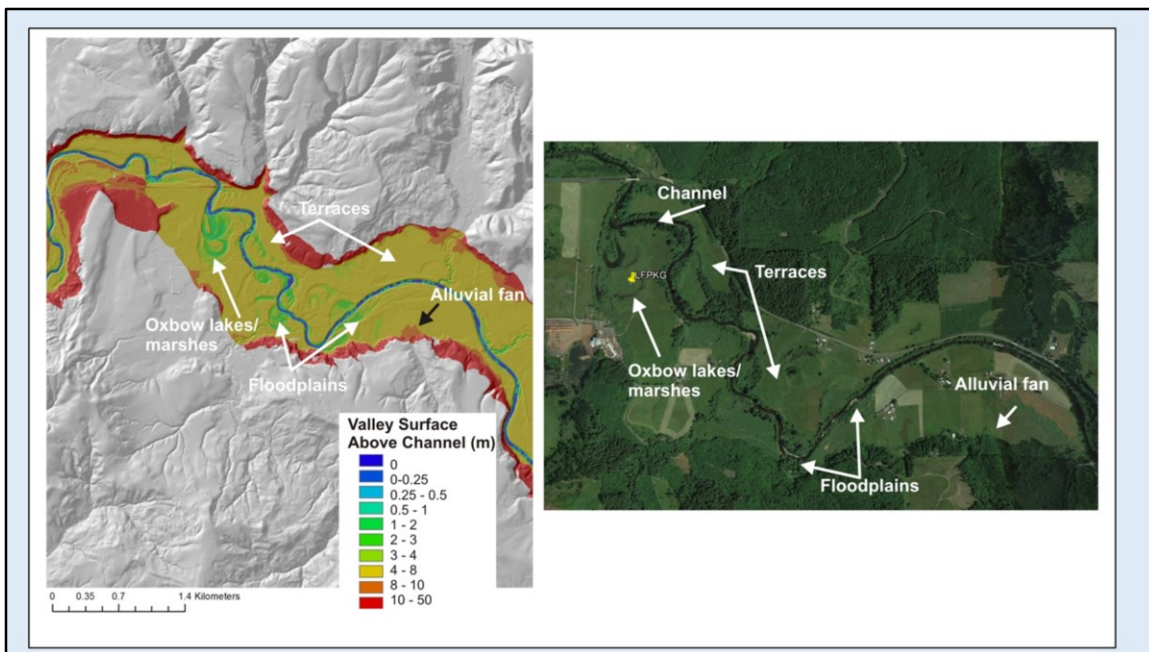

The LiDAR based floodplain maps provide considerably more detail (right panel, 1x, 2x etc. refers to valley elevations equivalent to one and two multiples of bankfull depths).

LiDAR can be used to resolve historically active floodplains, currently incised.

LiDAR can be used to resolve existing flood control dikes and abandoned (cutoff) floodplains.

LiDAR is effective at identifying landforms including channels, floodplains, oxbow lakes, marshes, terraces and alluvial fans. This information could be used to help prioritize restoration projects, particularly those designed to reconnect channels with their floodplains.

## Habitat modeling (salmon intrinsic potential, coho)

Visually compare, using 10 m and LiDAR DEMs, the difference between the spatial extent of the valley width at 5x bankfull depth and at 2x bankfull depth (the 2x valley surface is mapped using the latest technology available in NetMap along with LiDAR).

In the 10 m DEM, in most areas the 5x bankfull depth surface is wider than the 2x surface. This would result in less confined channels and in the IP model an over estimate of coho IP scores. The potential inaccuracies in predicted IP values using the 5x bankfull depth valley floor to calculate channel confinement using 10 m and LiDAR DEMs are shown in next slide. Use of older technologies can lead to a 100% overestimate in the highest IP scores ( $>0.75$ ), a significant underestimate in moderate IP scores ( $0.4 - 0.75$ ) and a larger proportions of low IP scores than actually exist.

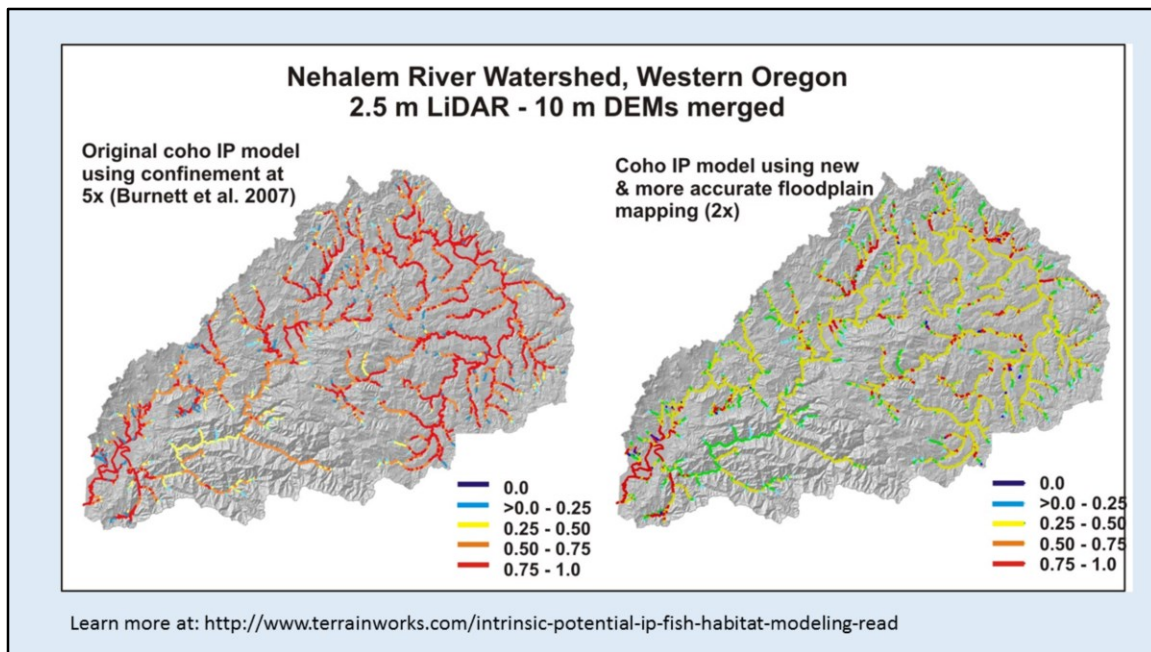

10 DEM

2.5 m LiDAR

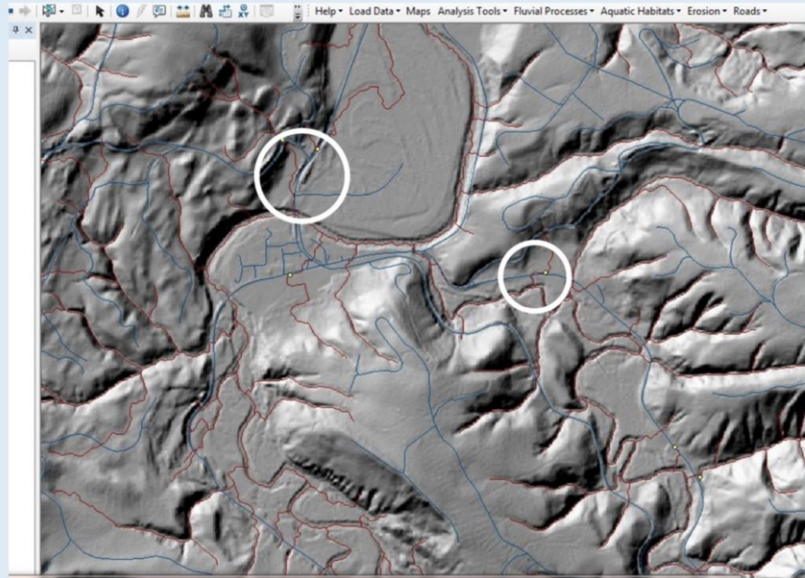

Use LiDAR with new floodplain mapping technologies to improve on the accuracy of intrinsic habitat potential modeling.

**Roads in LiDAR DEMs  
are often seen as  
topographic features  
and cause drainage  
diversions that need to  
be corrected**

Roads are seen as topographic features in LiDAR and the resulting drainage diversions need to be addressed when building the synthetic river network

TerrainWorks creates customized virtual watershed datasets that work with NetMap tools including utilizing LiDAR where available. If a watershed or landscape only has partial LiDAR coverage, we merge LiDAR with 10 m digital elevation data to create a seamless DEM.
